Main problem:

find a linear basis for the ring SR_n .

Approach:

ST algebras of SW arrangements

What is SR_n ?

The coinvariant ring:

$$R_n = \mathbb{Q}[x_1, x_2, \dots, x_n]/I^+$$

Superspace:

$$\mathbb{Q}[\mathbf{x}, \theta] = \mathbb{Q}[x_1, x_2, \dots, x_n, \theta_1, \theta_2, \dots, \theta_n]$$

where $\theta_i\theta_j = -\theta_j\theta_i$

Superspace:

$$\mathbb{Q}[\mathbf{x}, \theta] = \mathbb{Q}[x_1, x_2, \dots, x_n, \theta_1, \theta_2, \dots, \theta_n]$$

where $\theta_i\theta_j = -\theta_j\theta_i$

The superspace coinvariant ring:

$$SR_n = \mathbb{Q}[\mathbf{x}, \theta] / SI^+$$

Sagan and Swanson [SS24] conjectured the following \mathbb{Q} -basis of monomials for SR_n :

$$\mathcal{M} = \bigcup_{J \subseteq [n]} \{x^\alpha \theta_J : \alpha \leq (J\text{-staircase})\}$$

Sagan and Swanson [SS24] conjectured the following \mathbb{Q} -basis of monomials for SR_n :

$$\mathcal{M} = \bigcup_{J \subseteq [n]} \{x^\alpha \theta_J : \alpha \leq (J\text{-staircase})\}$$

Definition

A J -staircase is $(st(J)_1, st(J)_2, \dots, st(J)_n)$ where

$$st(J)_1 = \begin{cases} -1 & 1 \in J \\ 0 & 1 \notin J \end{cases}$$

and

$$st(J)_{i+1} = \begin{cases} st(J)_i & i \in J \\ st(J)_i + 1 & i \notin J \end{cases}$$

» Example

Let $J = \{2, 4, 5\} \subseteq [6]$. Then the J -staircase is $(0, 0, 1, 1, 1, 2)$.

» Example

Let $J = \{2, 4, 5\} \subseteq [6]$. Then the J -staircase is $(0, 0, 1, 1, 1, 2)$.

» Example

Let $J = \{2, 4, 5\} \subseteq [6]$. Then the J -staircase is $(0, 0, 1, 1, 1, 2)$.

So \mathcal{M} contains monomials

$$x_3 x_6 \theta_2 \theta_4 \theta_5$$

and

$$x_4 x_6^2 \theta_2 \theta_4 \theta_5$$

NOT

$$x_5^2 \theta_2 \theta_4 \theta_5$$

» Punchline

Elements of \mathcal{M} correspond to filled diagrams like

Staircase shape \longleftrightarrow skew-commutative θ factor

Staircase filling \longleftrightarrow commutative x factor

Conjecture [SS24]/Theorem [ACK⁺24]

$$\bigcup_{J \subseteq [n]} \{x^\alpha \theta_J : \alpha \leq (J\text{-staircase})\}$$

is a basis for SR_n .

What are SW arrangements and \mathcal{ST} algebras?

For the rest of the talk $S = \mathbb{Q}[x_1, x_2, \dots, x_n]$.

The colon ideal $(I : f)$ is the kernel of $\times f$. So

$$0 \rightarrow S/(I : f) \xrightarrow{\times f} S/I$$

is exact.

» Transfer principle

Rhoades and Wilson [RW23] showed that it suffices to show

$$\mathcal{M}(J) = \{\mathbf{x}^\alpha : \alpha \leq (J\text{-staircase})\}$$

is a basis for

$$S/(I^+ : f_J)$$

where

$$f_J = \prod_{j \in J} x_j \prod_{i > j} (x_j - x_i)$$

» Transfer principle

Rhoades and Wilson [RW23] showed that it suffices to show

$$\mathcal{M}(J) = \{x^\alpha : \alpha \leq (J\text{-staircase})\}$$

is a basis for

$$S/(I^+ : f_J)$$

where

$$f_J = \prod_{j \in J} x_j \prod_{i > j} (x_j - x_i)$$

Upshot

Trade a skew-commutative problem for a family of commutative problems.

Definition

An arrangement \mathcal{A} is called a *southwest arrangement* if its defining polynomial $Q(\mathcal{A})$ is a product of terms of a southwest-closed subset of $\tilde{\Phi}_n$.

The h -function of a southwest arrangement is the number of hyperplanes on each southeast diagonal.

» Example

\mathcal{A} defined by

$$x_1 x_2 (x_1 - x_2) (x_1 - x_3) (x_1 - x_4) (x_2 - x_3) (x_2 - x_4) (x_2 - x_5) (x_3 - x_4)$$

is southwest. It has h -function $(1, 2, 2, 3, 1)$.

» Non-example

The arrangement defined by f_J is not a southwest arrangement.

E.g. $J = \{2, 3\}$:

Definition

Let

$$\tilde{f}_J = \prod_{j \in J} \prod_{i > j} (x_j - x_i)$$

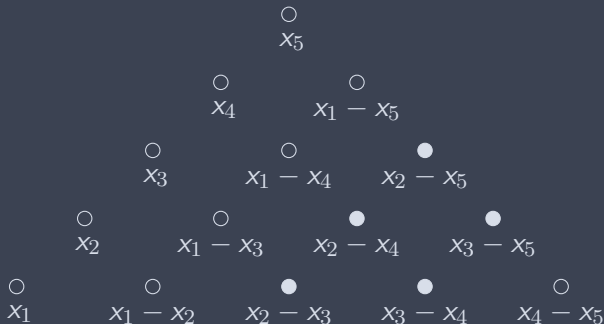

Note that \tilde{f}_J defines a southwest arrangement.

$$f_J = \prod_{j \in J} x_j \prod_{i > j} (x_j - x_i)$$

$$\tilde{f}_J = \prod_{j \in J} \prod_{i > j} (x_j - x_i)$$

» Example

If $J = \{2, 3\}$, then \tilde{f}_J corresponds to the southwest arrangement

Definition [AMMN19]

Let $\alpha : \text{Der}(\mathcal{A}) \rightarrow S$ be an S -module homomorphism.
Define the Solomon-Terao algebra to be

$$ST(\mathcal{A}; \alpha) = S / \text{im } \alpha$$

Theorem [ACK⁺24]

Let \mathcal{A} be an essential southwest arrangement in \mathbb{Q}^n with h -function $h(\mathcal{A})$. Let $\mathbf{i} : \text{Der}(\mathcal{A}) \rightarrow S$ be defined by $\partial_i \mapsto 1$. Then the monomials

$$\{x^\alpha : \alpha < h(\mathcal{A})\}$$

descend to a basis for $\mathcal{ST}(\mathcal{A}; \mathbf{i})$.

Definition

Let $J \subseteq [n]$ Let \mathcal{A}_J denote the hyperplane arrangement defined by

$$x_1 x_2 \cdots x_n \prod_{j \notin J} \prod_{i > j} (x_j - x_i)$$

Example

Let $J = \{2, 4\}$, then \mathcal{A}_J is

Lemma

The J -staircase is bounded above by the h -function of \mathcal{A}_J . In particular

$$h_k = \begin{cases} \text{st}(J)_k + 1 & k \notin J \\ \text{st}(J)_k + 2 & k \in J \end{cases}$$

Theorem [ACK⁺24]

$\mathcal{M}(J)$ is a basis for $S/(I^+ : f_J)$

Proof:

$$0 \rightarrow S/(I^+ : f_J) \xrightarrow{\times x^J} S/(I^+ : \tilde{f}_J) = \mathcal{ST}(\mathcal{A}_J, \mathbf{i})$$

is exact.

Theorem [ACK⁺24]

$\mathcal{M}(J)$ is a basis for $S/(I^+ : f_J)$

Proof:

$$0 \rightarrow S/(I^+ : f_J) \xrightarrow{\times x^J} S/(I^+ : \tilde{f}_J) = \mathcal{ST}(\mathcal{A}_J, \mathbf{i})$$

is exact.

Corollary

\mathcal{M} is a basis for SR_n , resolving conjecture of [SS24]

THANK YOU!
